Abstract

The goal of this study was to characterize the molecular mechanisms underlying cetuximab-mediated upregulation of HLA class I antigen-processing machinery components in head and neck cancer (HNC) cells and to determine the clinical significance of these changes in cetuximab-treated HNC patients. Flow cytometry, signaling studies, and chromatin immunoprecipitation (ChIP) assays were performed using HNC cells treated with cetuximab alone or with Fcγ receptor (FcγR)-bearing lymphocytes to establish the mechanism of EGFR-dependent regulation of HLA APM expression. A prospective phase II clinical trial of neo-adjuvant cetuximab was used to correlate HLA class I expression with clinical response in HNC patients. EGFR blockade triggered STAT1 activation and HLA upregulation, in a src homology-containing protein (SHP)-2-dependent fashion, more prominently in HLA-B/C than in HLA-A alleles. EGFR signaling blockade also enhanced IFNγ receptor 1 (IFNAR) expression, augmenting induction of HLA class I and TAP1/2 expression by IFNγ, which was abrogated in STAT1−/− cells. Cetuximab enhanced HNC cell recognition by EGFR53–861−specific CTLs, and notably enhanced surface presentation of a non-EGFR peptide (MAGE-3271–861). HLA class I upregulation was significantly associated with clinical response in cetuximab-treated HNC patients. EGFR induces HLA downregulation through SHP-2/STAT1 suppression. Reversal of HLA class I downregulation was more prominent in clinical responders to cetuximab therapy, supporting an important role for adaptive immunity in cetuximab antitumor activity. Abrogating EGFR-induced immune escape mechanisms and restoring STAT1 signaling to reverse HLA downregulation using cetuximab should be combined with strategies to enhance adaptive cellular immunity. Cancer Immunol Res; 3(8); 1–10. ©2015 AACR.

Introduction

The mitogenic activity of the EGFR has provided the rationale for the development of inhibitory strategies to block EGFR signaling, using tyrosine kinase inhibitors (TKI) and EGFR-targeted mAbs. This strategy has been shown to be effective, since the EGFR-specific mAb cetuximab has been approved by the FDA for head and neck cancer (HNC) and colorectal cancer (CRC). However, the precise mechanism, functional effect(s), and clinical significance of these findings have not yet been determined. EGFR signaling also influences the expression of immunologically relevant molecules in HNC cells, including STAT1-mediated HLA and antigen-processing machinery (APM) components (2–4), implying an important impact on adaptive immunity due to EGFR overexpression. However, the precise mechanism, functional effect(s), and clinical significance of these findings have not yet been determined.

Mechanism(s) of HLA class I APM component deficiency are still not clear, despite the importance of avoidance of lysis by cytotoxic T lymphocytes (CTL; refs. 5–9). Overexpression of EGFR, its ligands, and concomitant downstream signaling facilitates HNC proliferation by activating multiple pathways (10). Previously, we demonstrated the reversal of HLA class I and APM component deficiency in HNC using the STAT1 agonist IFNγ, which enhanced CTL-mediated lysis and induced a higher level of peptide:HLA complexes (6, 11–14). EGFR antagonism can also increase expression of HLA class I (14, 15) and proinflammatory cytokines (16). We have recently shown that SHP2, which operates downstream of EGFR and dephosphorylates p-STAT1, plays an important role in HLA-induced immune escape in HNC (17). Thus, we evaluated whether the EGFR–SHP2–STAT1 pathway might regulate HLA downregulation in HNC. The clinical significance of EGFR-induced HLA I downregulation is important, because recently induction of anti-EGFR T cells has been demonstrated in cetuximab-treated HNC patients (18, 19), supporting the crucial role for tumor cell...
downregulation of HLA antigen presentation by EGFR in evading
CTL elimination. Thus, the goal of this study was to investigate the
mechanism by which EGFR activation inhibits STAT1 activation
as well as the HLA class I APM pathway and resulting adaptive
antitumor immunity. We also exploited EGFR inhibition in
cetuximab-treated HNC patients as a strategy by which this
immune escape mechanism can be counteracted, linking HLA
upregulation with clinical response in a novel phase II trial of
neoadjuvant cetuximab therapy.

Materials and Methods

Cell lines

JHU-022, JHU-028, and JHU-029 were a kind gift from
Dr. James Rocco (Harvard Medical School, Boston, MA) in January 2007. SCC90, PCI-13, and PCI-15B were isolated from patients treated at the University of Pittsburgh Cancer Institute (Pittsburgh, PA) through the explant/culture method, authenticated, and validated as unique using STR profiling and HLA genotyping every 6 months (20, 21). 93-VU-147 T was a kind gift from Dr. Henning Bier (Technische Universität München, Munich, Germany) in October 2013. MCF-7 was a kind gift from Dr. Soldano Ferrone (Massachusetts General Hospital, Harvard Medical School, Boston, MA) in December 2012. 2FTGH (STAT1+/−) and U3A (STAT1−/−) were a kind gift from Dr. George Stark (Cleveland Clinic Foundation, Cleveland, OH) in December 2011. All cell lines were routinely tested and found to be free of Mycoplasma. All cell lines were cultured in IMDM GluMAX media with antibiotics (penicillin, 100 U/mL, streptomycin 100 μg/mL; Life Technologies), 10% FBS (Mediatech).

Patients and specimens

All patients signed an informed consent approved by the Institutional Review Board (IRB #99-06). Peripheral venous blood samples were obtained from HNC patients with stage III/IVA disease (Table 1), receiving neoadjuvant cetuximab on a prospective phase II clinical trial (UPCI 08-013, NCT 01218048). Tumors were biopsied immediately before, and again after 4 weeks of cetuximab therapy. Clinical response was analyzed by comparing paired CT scans pre/post-cetuximab, and quantifying tumor size in two dimensions and the cohort segregated into clinical “responders,” whose tumors grew during this therapy. “DNR,” who showed a reduction in tumor volume, or “nonresponders,” whose tumors grew during this therapy.

Cytokines and antibodies

IFNγ, InterMune and rhEGF, R&D Systems were purchased. LMP-2 (clone SY-1), TAP1 (NOBI), TAP2 (NOBI2), Tapasin (clone TO-3), calreticulin (TO-11), HLA-A (clone LGIII-147.4.1), and HLA-B/C (clone B1.23.2) were characterized previously (22). FITC-conjugated HLA-A/B/C (clone G4-6-2.6 or clone W6-32), APC-conjugated B-2m (clone 2M2), PE-conjugated IFNγ receptor α chain (clone G1R-208), p-STAT1 staining used PE-conjugated anti-p-STAT1 (Tyr701), APC-conjugated anti-STAT1 Ab (BD Biosciences), anti-STAT1 (C-24) polyclonal (pAb; Santa Cruz Biotechnology), anti-β-actin mAb (Sigma-Aldrich Inc.).

Quantitative real-time PCR

RNA from HNC cells was extracted using TRizol (Invitrogen; Life Technologies), purified by RNA-cleanup (Qiagen), Random hexamers, MuLV enzyme was used for cDNA synthesis (Applied Biosystems). PCR predeveloped probe for SHP2, HLA-B, STAT1, TAP-1, and β-actin were purchased from Applied Biosystem for TaqMan Gene Expression Assay. Real-time PCR (7700 Real-Time PCR System; Applied Biosystems) used the following conditions: denaturation at 95°C for 10 seconds, annealing at 60°C for 15 seconds, and extension at 72°C for 30 seconds. An initial denaturation step at 95°C for 5 minutes and final extension step at 72°C for 10 minutes were also included. Relative expression of the gene to endogenous control gene (β-actin/GUS) was calculated using the ∆Ct method: relative expression = 2−∆Ct, where ∆Ct = Ct (shp2) − Ct (β-actin/gus).

Immunoblotting

HNC cells were lysed in 1% Triton X-100 buffer with 1 mMol/L phenylmethylsulfonylfluoride, vortexed and centrifuged at 4°C, 16,100 × g for 15 minutes. The supernatant protein was normalized and 40 to 60 μg of protein were size fractionated through a 4% to 12% SDS-PAGE gel (Lonza), transferred to a polyvinylidene difluoride membrane (Millipore) and immunoblotted.

Immunohistochemistry

Slides were deparaffinized and rehydrated using a standard histology protocol. Diva Retrieval solution (Biocare Medical) and a Decloaking chamber at 124°C, 3:00 minutes, and cooled. The slides were placed on an Autostainer Plus (Dako) using 3% H2O2 for 5 minutes, CAS Block (Invitrogen) for 10 minutes, the HLA-A (HCA2 mAb) and HLA-B/C (HC-10 mAb) Abs were applied using a 1:6,000 dilution for 30 minutes. Both HLA-A and -B/C staining were quantified using a glass pixel count v9 algorithm (Aperio). IHC analysis using a semiquantitative scale (H-score) comprising the percentage of tumor cells positive multiplied by intensity (0–3 scale) was performed without prior knowledge of clinicopathologic data (minimum score = 0, maximum score = 300).

Chromatin immunoprecipitation assay

Starved HNC cells (24 hours, in AIM-V) before treatment (48 hours) were fixed with formaldehyde (1%, 10 minutes; Sigma-Aldrich Inc.), quenched with glycine (0.125 mol/L; Sigma-Aldrich Inc.), washed with PBS, and harvested. After centrifugation at 16,100 × g × 12 minutes, at 4°C, cells were lysed in SDS lysis buffer (Millipore) containing protease inhibitors. Chromatin was sheared by sonication for 12 seconds at 20% of maximum (Cole Parmer Instrument) to fragment DNA. STAT1 and IgG control sheared by sonication for 12 seconds, at 4°C, cells were lysed in SDS lysis buffer (Millipore) containing protease inhibitors. Chromatin was sheared by sonication for 12 seconds at 20% of maximum (Cole Parmer Instrument) to fragment DNA. STAT1 and IgG control sheared by sonication for 12 seconds, at 4°C. Protein-DNA cross-links were reversed at 65°C overnight. Initial denaturation: 95°C for 3 minutes, denaturation: 95°C for 15 seconds, anneal and extension: primer-specific temperature for 60 seconds; repeat steps b and c for 40 cycles. Commercially available “SimpleChIP Human TAP1 Promoter

Cetuximab-mediated EGFR inhibition differentially enhances expression of HLA class I alleles and APM components in a STAT1-dependent fashion. JHU-029 HNC cells were left untreated or were treated for 48 hours with the EGFR inhibitor mAb cetuximab (10 µg/mL). Levels of HLA-A alleles or HLA-B/C alleles were determined by FACS (A) or by qPCR (B), and levels of surface β2-m were measured by FACS (C). HNC cells were left untreated or were treated for 48 hours with the rhEGF (10 ng/mL), and levels of HLA class I (mAb W6/32) were determined by FACS (D). The levels of intracellular LMP2, TAP1, TAP2, tapasin, calnexin, and calreticulin (E) were measured by FACS. F, levels of HLA-A and HLA-B/C were evaluated in parental 2FTGH (STAT1+/+) and derivative USA (STAT1−/−) cells after treatment with EGFR siRNA plus cetuximab or control siRNA. In Fig. 1G, levels of intracellular β2-m were determined by FACS. H and I, cetuximab-induced STAT1 binding to the GAS element (IFNγ activation site) of the TAP1 promoter was measured using a chromatin immunoprecipitation (ChIP) assay. JHU-029 cells were treated with cetuximab (10 µg/mL for 30 minutes or 36 hours), IFNγ (10 U/mL) and cetuximab plus IFNγ (10 µg/mL, 10 U/mL) and enhanced binding of STAT1 at TAP1 promoter was determined by ChIP assay. Results represent mean ± SEM from three independent experiments. *P < 0.05; **P < 0.001; ***P < 0.0001. MFI, mean fluorescence intensity.

Figure 1.

Reversal of STAT1 Immune Escape by Cetuximab in HNC Cells

*51Cr cytotoxicity assay*

Cytotoxicity was determined using a 4-hour 51Cr release assay. Untreated and IFNγ-treated JHU-029 HNC cells were incubated in 100 µL of RPMI-1640 media with 25 µCi of Na51CrO4 (PerkinElmer) for 1 hour at 37°C and resuspended in RPMI-1640 media. Cells were washed (twice) and plated at indicated effector/target ratio (E/T ratio 40:1) in U-bottom 96-well plates. Cetuximab (10 µg/mL), anti-HLA class I mAb (50 µg/mL) was added in natural killer (NK) cell: JHU-029 coculture. Plates were incubated for 4 hours at 37°C in a 5% CO2 atmosphere. Controls for spontaneous (cells only) and maximal lysis (cells treated with 5% Triton-X) were included. Each reaction was performed in triplicate. Supernatants (50 µL) were collected and analyzed with a PerkinElmer 96-well plate gamma counter. Results were normalized with the formula of specific lysis = (experimental lysis – spontaneous lysis)/(maximum lysis – spontaneous lysis) × 100.

*siRNA transfections*

HNC was transfected with SHP2 or nontargeting siRNA control (Ambion) and lipofectamine-RNAi max (Life Technologies) according to the Lipofectamine-RNAi max instructions. SiRNA was used in this assay. SHP2 siRNA: 5'-GGAGACCGGUUGAUUCUCUFTT-3' (s) and 5'-AA GAAUCAACCGGUUCUCCTC-3' (as) EGFR siRNA: Custom siRNA oligo for wt EGFR, AACUCUGAGAAAIGAGUIdTdT
Control SiRNA: 5'-AGUACAGCAAACGAUACGGtt-3' (s) and 5'-CCGUAUCGUUUGCUGUACUtt-3'.

Statistical Analysis

Data were analyzed statistically using GraphPad Prism 4.0. A two-tailed unpaired or paired t test was used to calculate whether observed differences were statistically significant, defined as \( P < 0.05 \).

Results

Cetuximab-mediated EGFR inhibition differentially enhances expression of HLA class I alleles and APM components in a STAT1-dependent fashion

First, we determined the effect of EGFR signaling on the level of expression of two distinct alleles, HLA-A or HLA-B. Interestingly, incubation of HNC cells with the EGFR inhibitor cetuximab (10 \( \mu \)g/mL, 48 hours) led to increased HLA-B expression (~2-fold for protein and 9-fold increased transcription), to a greater extent than the expression of HLA-A (1.25-fold protein level, 2-fold increase in transcription; Fig. 1A and B). Similar upregulation was observed with \( \beta \)-2-m expression after EGFR inhibition (Fig. 1C). Although EGFR inhibition did not enhance free surface HLA-A heavy chains (HCA-2 mAb), elevated levels of free HLA-B/C heavy chains (HC-10 mAb) were observed (Supplementary Fig. S1A). Similarly, EGF stimulation inhibited HLA class I expression, inducing inhibition of HLA-B to a greater extent than of HLA-A (Fig. 1D and Supplementary Fig. S1B). In addition to upregulating HLA class I molecules, cetuximab treatment enhanced levels of intracellular APM components LMP2, TAP1/2, tapasin, calnexin, and calreticulin (Fig. 1E).
The STAT1 dependence of EGFR-driven HLA/APM downregulation in APM components LMP2, TAP1/2, and calnexin, indicating Cetuximab treatment increases IFNγ secretion and STAT1 activation (Supplementary Fig. S1A). A chromatin immunoprecipitation (ChIP) assay determined that cetuximab indeed induced binding of STAT1 to the TAP1 promoter (GAS element), providing physical evidence for transcriptional activation of APM pathway genes (Fig. 1H and I and Supplementary Fig. S1F).

Inhibition of the EGFR–SHP2 pathway induces STAT1 activation

Having shown that EGFR can regulate HLA expression in a STAT1-dependent fashion, we hypothesized that HLA downregulation due to autocrine or paracrine EGFR activation may drive SHP2 phosphatase activation and resulting STAT1 suppression (13, 17). To investigate this possibility, we treated JHH-029 HNC cells with cetuximab (10 µg/mL, 24 hours) and found that cetuximab treatment significantly decreased SHP2 expression, whereas IFNγ treatment (10 IU/mL) as a positive control had no effect on SHP2 expression. The combination of cetuximab and IFNγ reduced SHP2 levels, when compared with untreated HNC cells (Supplementary Fig. S2A). We then measured the expression of p-STAT1 (Tyr701) and total STAT1 after cetuximab alone or plus IFNγ treatment. After cetuximab treatment, a slight increase in the level of p-STAT1 (Tyr701) was observed (from 1% to 7% p-STAT1+ cells), whereas a more prominent increase in the level of total STAT1 was observed (~2-fold higher mean fluorescence intensity vs. untreated). IFNγ treatment strongly increased expression of both p-STAT1 (Tyr701; 1%/–62%) and total STAT1 (~7.9-fold increase in MFI vs. untreated). Interestingly, cetuximab treatment augmented the ability of IFNγ to induce p-STAT1 (from 62% to 81% positive cells) and total STAT1 (~12-fold higher MFI vs. untreated; Fig. 2A–C). A similar observation was confirmed with immunoblotting (Supplementary Fig. S2B) and STAT1 transcript analysis (Supplementary Fig. S2C). We also evaluated STAT1 and HLA expression after cohibiting SHP2 and EGFR (using siRNA or cetuximab) to bypass EGFR. SHP2 phosphatase depletion using siRNA (17) enhanced cetuximab-induced p-STAT1 (Tyr701), as well as total STAT1, expression suggesting that high SHP2 expression downstream of EGFR in HNC cells prevents STAT1-mediated signaling. Indeed, the combination of SHP2 siRNA and cetuximab treatment strongly enhanced cetuximab-mediated STAT1 upregulation (Fig. 2D–F and Supplementary Fig. S2D).

Cetuximab treatment increases IFNγ receptor 1 expression

Because EGFR signaling might downregulate IFNγ receptor1 (IFNγRI; ref. 25), providing a mechanism for synergistic effects of EGFR blockade with IFNγ for STAT1-mediated HLA upregulation, we evaluated levels of IFNγRI after cetuximab treatment. Indeed, cetuximab increased the expression of IFNγRI in several HNC cell lines tested, in an EGFR-dependent fashion (Fig. 3A–C). To test the hypothesis that EGFR density is important in regulating IFNγRI, we used cetuximab and EGFR siRNA to abolish EGFR-proximal signaling (Supplementary Fig. S2E), which independently showed an increase of IFNγRI expression (Supplementary Fig. S2F). As expected, the combination of cetuximab treatment plus EGFR siRNA knockdown showed the most pronounced effect on IFNγRI downregulation (Supplementary Fig. S2F).

Cetuximab-activated NK cells and IFNγ increase expression of HLA class I APM pathway

Because IFNγ increases expression of HLA class I and APM components in HNC cells, and because NK cells secrete IFNγ after recognizing cetuximab-coated HNC cells in the tumor microenvironment (18, 26), we considered the impact of cetuximab-activated NK cells during coculture with HNC cells (19, 27). Under these conditions, even more robust expression of HLA-A and HLA-B/C was observed (Fig. 4A), particularly when both NK cells and cetuximab were present. As shown, IFNγ released from cetuximab-activated NK cells further evoked HLA-A and HLA-B/C upregulation, because an IFNγ-neutralizing Ab abrogated the beneficial effect of NK-cell treatment in both cases (Fig. 4A). An IgG2α, anti-EGFR mAb panitumumab failed to activate NK cells under similar conditions (19). Again, HLA-B/C alleles showed a more pronounced enhancement after cetuximab treatment or by cetuximab-activated NK cells (~1.93-fold and ~1.78-fold induction), in comparison with...
HLA-A. In support of a common pathway, the STAT1 inhibitor fludarabine (23) abrogated HLA-A and HLA-B/C upregulation in response to cetuximab, EGFR siRNA, or IFNγ treatment (Fig. 4B). We further evaluated the contribution of IFNγ-induced HLA class I expression to NK-cell–mediated antitumor effects (Fig. 4C). Cetuximab-mediated antibody-dependent cellular cytotoxicity (ADCC) was significantly enhanced against IFNγ-treated HNC targets, and blocking HLA class I with W6/32 mAb (pan-HLA class I mAb) augmented cetuximab-mediated ADCC (Fig. 4D).

SHP2 inhibition robustly enhances cetuximab-mediated tumor antigen presentation

Next, we evaluated the combined effect of cetuximab and IFNγ on the expression of free HLA-A (HCA-2 mAb) or free HLA-B (HC-10 mAb), surface HLA-A and HLA-B/C, surface pan-HLA class I (HLA-A/B/C), or β2-m. Cetuximab alone increased HLA-A expression by approximately 1.25-fold, in comparison with an approximately 1.45-fold increase for HLA-B/C (Fig. 5A); IFNγ alone increased HLA-A expression by approximately 3.9-fold in comparison with an approximately 6.9-fold increase for HLA-B/C when compared with that of no treatment. The most prominent upregulation of HLA-A and HLA-B/C (~5 fold and ~9.5 fold vs. untreated, P < 0.0001) was observed when the combination of IFNγ and cetuximab was used. We also found greater HLA-B versus HLA-A allele transcripts after treatment with cetuximab, with IFNγ alone, or with cetuximab plus IFNγ (Fig. 5B and Supplementary Fig. S3A–S3E).
Because cetuximab treatment enhanced the expression of LMP2, and TAP1/2 (Fig. 5C and Supplementary Fig. S4A–S4B), we investigated whether the enhanced HLA class I APM components enhanced surface presentation of tumor antigens (TA). We used a novel mAb (12b6), recognizing the HLA-A2:MAGE-3271–279 complex (Supplementary Fig. S5A–S5B), to quantitatively measure levels of surface HLA–TA complexes. Cetuximab enhanced the HLA-A2:MAGE-3271–279 complex (P < 0.001; Fig. 5D and E), which was even more robust after IFNγ treatment (P < 0.0001). Interestingly, the combination of cetuximab and IFNγ treatment evoked the highest level of HLA-A2:MAGE-3271–279–peptide complexes (P < 0.0001). Indeed, the combination of SHP2 siRNA and cetuximab treatment strongly enhanced cetuximab-induced HLA-A and HLA-B/C expression, most prominently in the latter alleles (Fig. 5F and Supplementary Fig. S5C). SHP2 depletion in HLA-A2+ HNC cells also enhanced HLA-A2:MAGE-3271–279–peptide presentation after cetuximab treatment (Fig. 5G and Supplementary Fig. S5D), whereas no binding was observed in HLA-A2− or TA− HNC cells (Supplementary Fig. S5E–S5F).

Cetuximab neoadjuvant therapy enhances expression of HLA class I in HNC patients

In a novel phase II prospective clinical trial, tumors from HNC patients were biopsied before and after 4 weeks of single-agent neoadjuvant cetuximab therapy. HLA class I expression was measured semiquantitatively using IHC and digital image analysis, and correlated with clinical response by paired pre/post CT scans to identify clinical “responders.” After cetuximab therapy,
both HLA alleles and STAT-1 were upregulated in the clinical responders ($n = 7$) but not in nonresponders ($n = 17$; Fig. 6A–D) to EGFR-specific mAb therapy.

**Discussion**

In HNC, low levels of HLA class I and APM component expression preclude effectiveness of CTL responses in mediating tumor elimination (11), and this mechanism of immune escape is a consequence of diminished STAT1 activation generated by the overexpression of SHP2 (17). Multiple pathways are linked with SHP2 functions in HNC, primarily the EGFR–SHP2 pathway. Because of the frequent overexpression of EGFR, which is a poor prognostic factor in HNC, constitutive activation of this pathway may greatly facilitate an “immune-escape” phenotype through suppression of p-STAT1–mediated expression of the HLA–APM pathway. This study sheds light on the mechanism(s) responsible for the diminished TA processing and presentation due to suppression of STAT1 and HLA class I APM components in HNC, which may be reversed through EGFR blockade, IFNγ release due to cetuximab-activated NK cells, or both. The effect is likely to have a beneficial impact on the clinical course of the disease in HNC patients treated with cetuximab. Recently, we have shown that in HNC patients, cetuximab induces cross-priming of EGFR-specific CTls by NK:DC cross-talk (18, 19). However, the determinants of TA recognition by CTls...
may benefit cetuximab-mediated clinical responses. Intriguingly, processing and presentation of HLA class I peptide complex is an intricate process (28), and polymorphism in HLA class I alleles (29), their differential levels, and the dynamic role of APM components represent important immune-escape mechanisms from adaptive immunity in cancer (19, 29). Using a novel HLA-A2:MAPE–3–specific mAb, we demonstrated quantitatively enhanced TA presentation in HNC cells, which is critical for CTL lysis. Thus, the likelihood of generation of a greater repertoire of TAs (“antigen spreading”) appears to result from EGFR blockade using cetuximab, perhaps due to IFNγ-induced antigen presentation along with upregulated HLA alleles. Enhanced recognition of the peptide–HLA-A2 complex using the combination of cetuximab and IFNγ could be monitored diagnostically as a measure of Th1-biased immune responses. However, in light of superior restoration of HLA-A and HLA-C with cetuximab, greater characterization of HLA-B–restricted TAs is also warranted, particularly during cetuximab-based immunotherapy. These effects could be overcome by a greater drop in HLA class I expression after EGFR treatment of HNC cells. The effect of HLA upregulation on reduced cetuximab-mediated ADCC supports a moderate impact of NK-cell inhibitory, killer immunoglobulin–like receptors (KIR) and the tumor cell/HLA class I interaction during cetuximab-mediated ADCC.

Polymorphism of HLA class I alleles may play a dominant role in regulating NK-cell effector function. Interaction of a few NK-cell inhibitory receptors with a specific HLA allele plays an important role in NK-cell–mediated antitumor responses. Inhibitory KIRs have higher affinity for HLA-B than for HLA-A (29). This suggests the strong possibility that HLA-B, which interacts with KIR, may have a negative impact on NK-cell stimulation (29), and HNC may become more resilient to further NK-cell attack (30, 31). HLA-B is most often loaded with antigenic peptides (32). In the HNC cell lines used in our study, IFNγ induced HLA-B/C more strongly than HLA-A (32, 33), a result that had been rarely reported previously. This observation reflects the fact that EGFR signaling in combination with p-STAT1 suppression by SHP2 has overwhelmingly negative effects on immunogenic TA-peptide presentation, abrogating the generation, loading, and presentation on surface HLA class I/TA peptide complexes, which are necessary for CTL lysis.

Cetuximab induces EGFR-specific CTL responses in some HNC patients (18), whereas clinical response to cetuximab is only observed in a subset of patients (~20%; refs. 34, 35). The effects of concerted antitumor immune responses involving NK cells, NK–DC cross-talk, and CTL responses (18, 19, 36, 37), along with upregulation of HLA class I and IFNγR1, may contribute to response to cetuximab therapy. Indeed, we observed STAT1, HLA class I upregulation in cetuximab-treated patients in a novel neoadjuvant trial, suggesting that EGFR inhibition and/or IFNγ release contributes to the reversal of HLA downregulation. Results from recent studies also indicate an immunosuppressive effect of EGFR signaling on STAT1-dependent HLA class I and CIITA genes (38, 39). However, HLA class I and CIITA are modulated by both total STAT1 and p-STAT1 (40, 41), and a recent report also indicates that EGFR inhibitors reduce PD-L1 expression in lung tumors (42), suggesting multiple immune-escape mechanisms mediated by EGFR signaling.
